(Rø 1924; 1924)

2010; 2012).

1. 1996; 2008),

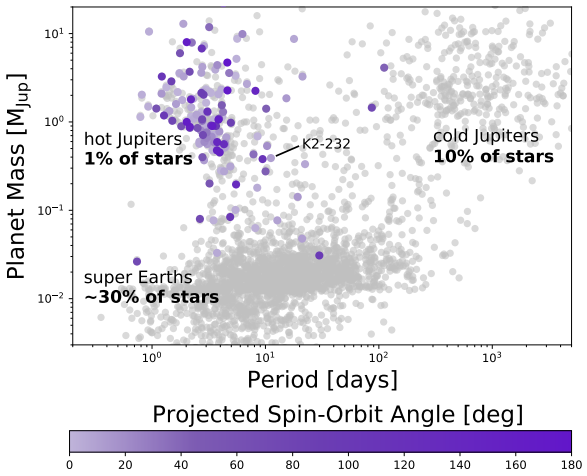

Figure 1. An up-to-date mass-period diagram of currently known exoplanets. Planets with Rossiter-McLaughlin (including Doppler tomography) measurements drawn from the TEPCat catalog (Southworth 2011) are shown as points color-coded by their observed spin-orbit angles, while planets without stellar obliquity measurements are depicted as gray dots. The majority of planets with existing Rossiter-McLaughlin measurements are hot Jupiters, which span a wide range of stellar obliquities. In this work, we have expanded the list of spin-orbit measurements to include a new warm Jupiter system: K2-232.

[illegible] (Winn & Morton 2003; Fabrycky & Winn 2007; Naoz 2016), [illegible] (Wu & Lithwick 2011; Petrovich 2015).

2. Observations of [illegible] *unrelated* [illegible] [illegible] (Batygin 2010), [illegible] [illegible] (Rogers 2012), [illegible] [illegible] (Lai 2011), [illegible] [illegible] (Batygin 2011; Boué 2014).

Observations — [illegible] [illegible] 10 [illegible] — [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] (Dong 2013). Figure 2. Spectroscopic radial velocities of K2-232 measured with the APF, as a function of orbital phase (minutes from mid-transit) along with the best-fitting Rossiter-McLaughlin model (red-dashed line). The radial velocity offsets in each of the datasets have been removed prior to fitting the combined and phased data. The green and maroon points are the radial velocities from the 29 October 2019 and 4 January 2020 transit observations, respectively. The lower panel shows the residuals between the observed data and the best-fitting model. The small structures remaining in the residuals are likely caused by stellar noise and variations in atmospheric extinction due to the presence of clouds at the end of night on 4 January 2020

.

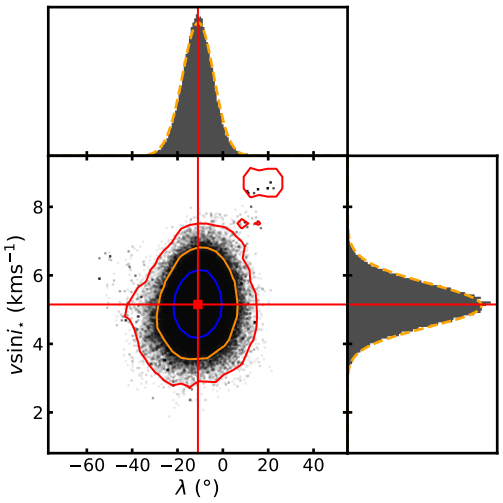

Figure 3. Posterior distributions of the projected spin-orbit angle (λ) and projected stellar rotational velocity ($v \sin i_\star$) for K2-232 from the Markov Chain Monte Carlo Rossiter-McLaughlin simulation. The posterior points inside the blue, yellow, and red contours lie within the 1σ, 2σ, and 3σ confidence regions, respectively. We have marginalized over λ and $v \sin i_\star$ and fit each with a Gaussian. The red square denotes the preferred model solution for λ and $v \sin i_\star$ as given in Table 2.

3. SPIN-ORBIT ANGLE DETERMINATION

[1] https://github.com/MNGuenther/allesfitter

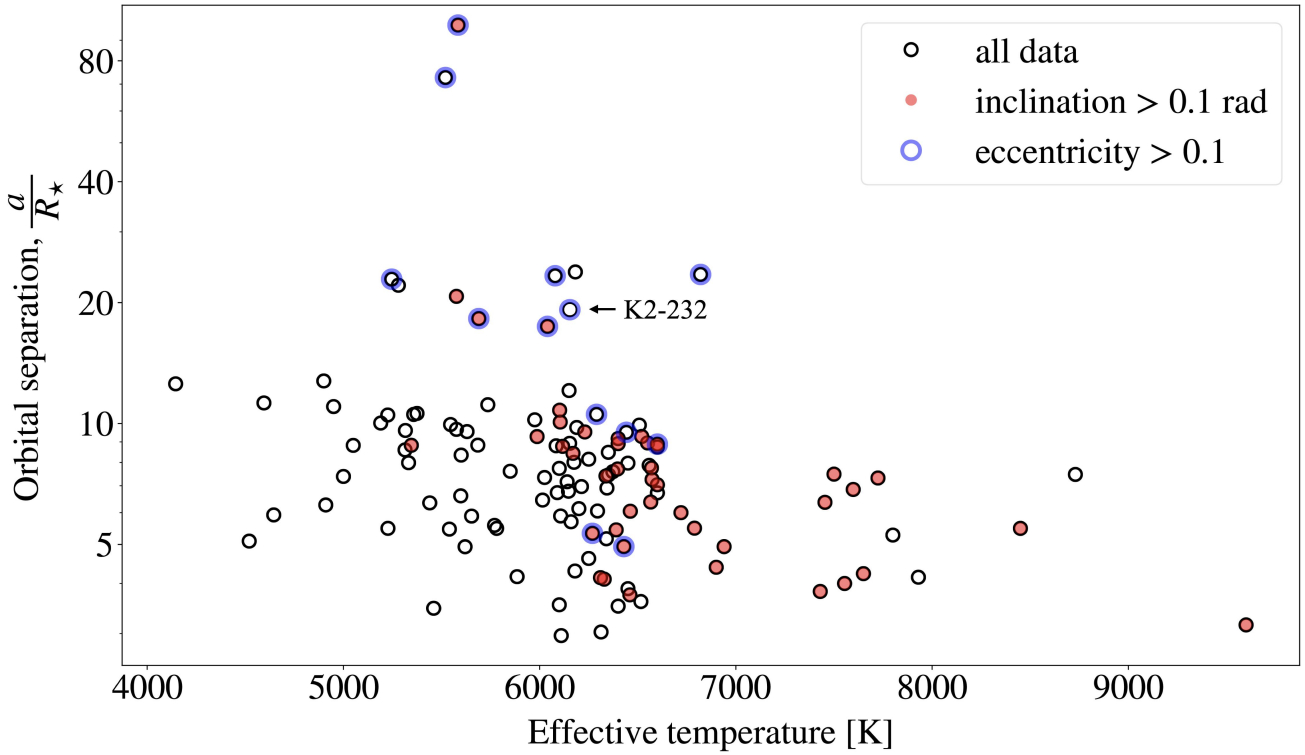

Figure 4. Key variables that may affect tidal dissipation rates, provided for all the transiting giant planets ($M_{\rm p} > 0.3\,M_{\rm Jup}$) for which the Rossiter-McLaughlin effect has been reported. The horizontal axis shows effective temperature of the host star, and the vertical axis shows the dimensionless orbital separation (semimajor axis divided by stellar radius). Red points indicate the sky-projected obliquity exceeds 0.1 rad (5.7 deg), and blue encircled points indicate the orbital eccentricity exceeds 0.1, in both cases with at least 3-σ confidence. The scarcity of misaligned or eccentric systems with $a/R_\star \lesssim 10$ and $T_{\rm eff} \lesssim 6000\,$K suggests that tidal effects have damped the obliquity and eccentricity of at least some of those systems.

Argument of periastron ω (deg)	...	$206.3^{+8.0}_{-9.4}$	$206.3^{+7.8}_{-9.8}$	$206.7^{+7.8}_{-9.0}$
Limb darkening; u_1	...	$0.276^{+0.061}_{-0.053}$	$0.272^{+0.058}_{-0.052}$	$0.273^{+0.059}_{-0.053}$
Limb darkening; u_2	...	$0.461^{+0.098}_{-0.10}$	$0.468^{+0.096}_{-0.10}$	$0.464^{+0.097}_{-0.10}$

[a] The uniform priors are presented in the form of three numbers: the first number is the lower bound, the middle number is the initial guess, and the last number is the upper bound.

[b] We provided a reference mid-transit epoch for T_0. During the fit, `Allesfitter` can shift epochs to the data center to derive an optimal T_0.
