**Key words:**

Waste; steel industry; material flows; socio-material; problem waste

Received 19 September 2011  
Accepted 22 March 2012

**Abstract** – This paper, delivered at the SAM2 Conference in Nantes, France, in April 2008, addresses issues of material flows in a selection of modern steel plants, especially the generation of wastes, from a social sciences perspective. I analyse key factors structuring waste management decisions through the case of "problem" wastes arising at a steel company's plants. I discuss how some materials come to be construed as more problematical than others from a material and technological point of view, but also by taking into account organisational and legislative issues, in order to show that the construction of the "waste" category needs to be envisioned as resulting from a matrix of socio-material causes.

1 The steel industry has undergone pro-  
2 found corporate changes of late with  
3 high profile takeovers that are part of  
4 a shift from the West to developing coun-  
5 tries of the centre of gravity of the industry.  
6 This change is also illustrated by the rapid  
7 rise of China (and, increasingly, India) both  
8 as a consumer and producer of steel, and  
9 its increasing importance on the market for  
10 raw materials. Steel is probably the mate-  
11 rial of the globalised world and its icons (the  
12 aeroplane, the cargo ship, the automobile), it  
13 is extremely flexible in its applications, and  
14 fits into the current discourse on "sustain-  
15 ability" because it is recyclable. However,  
16 paradoxically, steel is more or less absent  
17 from research agendas in the social sciences:  
18 it tends to be neglected as an "old", "dirty"  
19 industry that has nothing to teach us and  
20 that we have nothing to say about. In this  
21 paper, I show that this industry can tell us  
22 a lot about the social, economic and envi-  
23 ronmental aspects of the transformation of  
24 materials and the production of wastes in  
25 the context of globalisation. This industry  
26 offers an opportunity to visualise flows of  
27 materials and their fates and connect them  
28 to the overarching dynamics structuring our  
29 world today. Likewise, I hope to show that  
30 the industry can also benefit not just from

the raw input of technology, but also from 31  
a more reflexive approach supported by re- 32  
search in the social sciences: in other words, 33  
I would like to make the case for greater col- 34  
laboration between industry and the social 35  
sciences. 36

I start with an overview of the steel in- 37  
dustry and the production of steel, in order 38  
to frame the reflection in terms of flows of 39  
materials, and show how this can be for- 40  
malised to convey the complexity of the pro- 41  
cesses involved in the industry, and the parts 42  
of the process where materials can become 43  
wastes. Then, in a second part, I focus on spe- 44  
cific materials that have come to be seen as 45  
problematical certain segments of the steel 46  
industry<sup>1</sup>: how and why do some materi- 47

<sup>1</sup> Due to the sensitive nature of some of the information and in order to comply with the ethical requirements of academic research, the results presented here are strictly anonymous. Research, including interviews of executives and shop-floor personnel, was carried out at several major steel plants of different companies in Europe and Asia, and complemented by interviews with steel industry experts and a comprehensive literature review to put these data in global perspective. Many of the issues addressed here apply to some degree to the global steel industry, so the preservation of the anonymity of sources of data is not believed detrimental to the reader. All ideas

1 als become “problem wastes”? What does  
 2 this tell us about wider dynamics of ma-  
 3 terial flows and the social construction of  
 4 the “waste” category? Ultimately, what does  
 5 it reveal about the factors structuring by-  
 6 product and waste management in the in-  
 7 dustry today?

8 **1 Part I: the steel industry:**  
 9 **material flows, production,**  
 10 **and wastes**

11 In this first part, I build a model of the  
 12 steel industry today in order to understand  
 13 flows of materials, as well as production, by-  
 14 products, residues, and wastes.

15 Beyond steelmaking *stricto sensu*, there  
 16 are other activities involved in the process  
 17 of making steel, each with their by-products  
 18 and wastes. For instance, cokemaking, with  
 19 its associated dusts and gases, and the gener-  
 20 ation of large quantities of coke fines, as well  
 21 as flows of contaminated water. There is also  
 22 sintering, which generates highly toxic dusts  
 23 and where dioxins are also a concern. There-  
 24 fore, simply analysing the steps of steelmak-  
 25 ing itself is not enough to understand the full  
 26 impact of the production of steel or to get a  
 27 complete picture of waste management in  
 28 the industry. However studying all these as-  
 29 pects would be too vast an enterprise, so,  
 30 while acknowledging these steps of the pro-  
 31 cess and their contribution to overall waste  
 32 production, I focus on the most problemat-  
 33 ical points of the production process, both  
 34 within and without the steelmaking process  
 35 itself.

36 **1.1 Materials and their fates:**  
 37 **formalising flows**

38 I focus here on what happens to the materi-  
 39 als in the production of steel: how they are  
 40 transformed into products, by-products and  
 41 wastes, based on the mass balance principle  
 42 of “what comes in must come out”.

within the paper are the personal opinion of the  
 author and are not sanctioned by any institution,  
 organisation or other third party, and specifically  
 not the University of Southern Queensland.

**(a) The examples of the coke ovens** 43  
**and the sinter plant** 44

Let us look at two crucial steps of steelmak- 45  
 ing, to identify what exactly is produced in 46  
 each of these steps. By produced, I mean not 47  
 only the desired (aimed-for) material at each 48  
 step of the process (sinter, liquid iron, steel 49  
 etc.) but also the by-products of each step, 50  
 which, depending on whether it is reused 51  
 or not, can, *de facto*, become “waste”, or 52  
 start to migrate towards that category, via 53  
 treatment, storage etc. For the moment, the 54  
 widely accepted definition of waste suffices: 55  
 “a substance that a given agent does not, or 56  
 does not intend to, reuse in the foreseeable 57  
 future”. Thus, stockpiling, even under the 58  
 pretense of “future” use, will be considered 59  
 waste when that “future” use is not clearly 60  
 defined given today’s technologies. 61

First, the coke plant. Coke is produced 62  
 from the destructive distillation of coal at 63  
 high temperatures. Large quantities of gases 64  
 are emitted, namely CO (carbon monoxide), 65  
 CO<sub>2</sub>, SO<sub>2</sub>, NO<sub>2</sub> etc. However, a lot of this gas 66  
 is actually reused, either at the coke plant it- 67  
 self, or circulated to other parts of the steel 68  
 plant, such as the blast furnace (BF). CO, for 69  
 instance, is burnt to produce the heat re- 70  
 quired. Also, large quantities of dust arise 71  
 from the production of coke; however, a con- 72  
 siderable proportion of this extremely abra- 73  
 sive coke dust is reused via the sinter plant. 74

The sinter plant combines ore, coke and 75  
 lime in sintered pellets that can be fed into 76  
 the BF to enhance and stabilise its operation, 77  
 ensuring optimal hot metal quality. The sin- 78  
 ter plant produces large quantities of gases 79  
 and toxic, heavy-metal-laden, dusts. How- 80  
 ever, the sinter plant also acts as a “recy- 81  
 cling” plant: dusts from other parts of the 82  
 production process (cokemaking, BF, BOF 83  
 (basic oxygen furnace), rolling... as well as 84  
 dusts generated in the sinter plant itself), as 85  
 long as they contain Fe (iron), C (carbon) 86  
 and/or fluxing agents, can be recirculated 87  
 in the sinter strand, thereby contributing to 88  
 loop closure. Thus, although the sinter plant 89  
 itself generates a lot of dusts, they are main- 90  
 ly reused in the sintering process, and the sin- 91  
 ter plant can take on a lot of the by-product 92  
 burden of the whole plant, as will be seen in 93  
 more detail later. 94

1 Therefore, such processes, although they  
2 do generate wastes and emissions and can be  
3 a concern, will not be the focus here, because  
4 they witness a lot of recirculation of their  
5 products in other parts of the process, and  
6 thus do not really pose a problem overall.

7 A more abstract way of looking at the  
8 flows of materials in steelmaking goes like  
9 this: what (typically) enters a steel plant and  
10 the various parts of the production process,  
11 and how material flow from one part to  
12 another. This is the Material Flows Analy-  
13 sis (MFA) grounded in industrial ecology:  
14 What average quantities of materials are pro-  
15 duced at each step of the process? How do  
16 they circulate between different parts of the  
17 process? And how much eventually ends up  
18 in the "waste" category, after having been  
19 a raw material, a by-product, or a residue?  
20 Indeed, a discussion of all these potentially  
21 confusing terms is necessary to understand  
22 how and why waste becomes waste – the "bi-  
23 ography" of waste –, through which steps,  
24 and how this is subject to historical and spa-  
25 tial variations linked to technologies, tech-  
26 niques, practices, but also the very material  
27 characteristics of the "stuff" of steelmaking.

### 28 **(b) Typical flows at plant level**

29 The following diagram ("Typical flows in a  
30 steel plant") shows the flows of materials  
31 from the different parts of the process, for  
32 a typical steel plant. It clearly shows both  
33 the recirculation and the loss of materials  
34 in the production process. What we notice  
35 with this diagram is the variability (or the  
36 fuzziness of our knowledge) of flows for  
37 some materials, and the stability (or more  
38 precise knowledge) of others. For instance,  
39 the production of BF slag appears to be sta-  
40 ble at 240 kg per tonne of crude steel, in  
41 any given plant, whereas the reflow of sin-  
42 ter, an essential aspect in our understanding  
43 of loops in the production process, varies  
44 from 275 to 550 kg per tonne of crude steel, a  
45 very wide margin indeed, reflecting varying  
46 practices in steel plants, but also probably  
47 the difficulty in tracking such dynamics. In-  
48 deed, what comes "out", such as slag, and  
49 ends its cycle there (and especially more so  
50 when it is, such as slag, a valuable and al-  
51 most readily saleable commodity), is easier  
52 to account for than materials that "pop in"

and "pop out" of a process, with series of 53  
losses, gains, and combinations that entail 54  
complex material changes. Such a complex 55  
process is evident in the case of the vari- 56  
ous gases, subsequently transformed in the 57  
treatment process into liquids (sludges) and 58  
solids (dusts, filter cakes). We can expect 59  
important losses in such a conversion pro- 60  
cess, and indeed, the figures for the pro- 61  
duction of these residues vary considerably, 62  
emphasizing a sort of fuzzy accountability 63  
when it comes to unwanted and (up to re- 64  
cently at least) unvalued materials that were 65  
traditionally candidates for a holes-in-the- 66  
ground end: thus, the quantities of waste are 67  
also a function of society's interest, or lack 68  
thereof, in certain materials. 69

### 70 **1.2 Conclusions of part I**

71 We have seen in this section, albeit in a 71  
very summarised form, how important it is 72  
to visualise the production of steel as a se- 73  
ries of flows and counter-flows. Contrary to 74  
the assumed vision of production in gen- 75  
eral whereby material flow in one direction 76  
(from the "beginning" of the process to its 77  
"end", i.e. finished steel) we see that these 78  
flows often form (more or less closed) loops, 79  
with materials returning to "earlier" stages 80  
of production: thus, there is a fair deal of "re- 81  
cycling" in the very literal sense of things be- 82  
ing recirculated, in cycles. In that sense, a lot 83  
of by-products do not become waste. Also, 84  
the transformations are numerous and mul- 85  
tifaceted, with materials going from solids 86  
to fluids to gases, with all the transforma- 87  
tions and losses attributable to entropy, mak- 88  
ing it arduous to precisely track everything 89  
that is going on. However, we can zero in 90  
on some specific points of the process where 91  
some materials end their course, for a variety 92  
of reasons, thereby becoming, for all intents 93  
and purposes, wastes. 94

## 95 **2 Part II: identifying and** 96 **analysing "problem" wastes** 97 **in the industry**

### 98 **2.1 What makes a material** 99 **"problematical"?**

100 In this second part, I look at the factors  
101 structuring the way selected wastes are pro-

F. MacKillop: *Revue de Métallurgie*

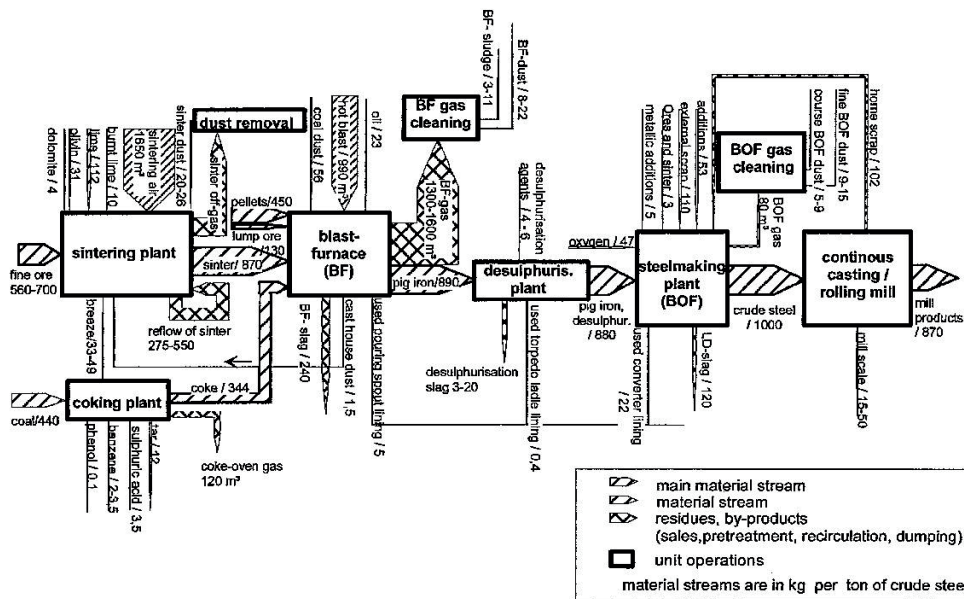

Fig. 1. Source : Geyer et al. [1, 2]<sup>3</sup>.

1 duced, conceived, and managed in the steel  
 2 industry today, and how those materials  
 3 are framed, discursively and in practices, as  
 4 “problem” wastes.

5 We have already seen that many by-  
 6 products are re-used, sometimes almost en-  
 7 tirely, in other parts of the process, and are  
 8 therefore not to be considered wastes; the  
 9 sinter plant is one of the main foci of this  
 10 recirculation. There have also been other de-  
 11 velopments in this field, such as briquetting,  
 12 whereby pellets can be produced from var-  
 13 ious dusts and sludges and then be used in  
 14 the BOS plant both as a raw material and a  
 15 coolant. Thus, the term “waste” is not actu-  
 16 ally applicable to many substances that were  
 17 once seen as such, as they are put to use ei-  
 18 ther in the production process or in other  
 19 industries : in other words, materials have a  
 20 history, and in this history, they can flow in  
 21 and then out of the “waste” category. Thus,  
 22 few materials can be essentialised under a  
 23 monolithic label of “waste”. For instance, it  
 24 is very significant that, in the [3] Interna-  
 25 tional Iron and Steel Institute (IISI, an indus-  
 26 try body) study (IISI [3]), the only “wastes”  
 27 studied in the global steel industry were BF  
 28 and BOS slags, which are not particularly  
 29 difficult, from a material point of view, to  
 30 deal with, especially since they have many  
 31 commercial applications. The point is rein-

forced by the fact that BF slag has been re-  
 32 cently reclassified by the EU as a by-product,  
 33 not a waste; this also shows the great inertia  
 34 in attitudes towards what constitutes valu-  
 35 able materials or not. In the [4] IISI (IISI 1994)  
 36 study, the list of wastes was much longer,  
 37 and much more problematical. This study,  
 38 however, still contained assertions that are  
 39 unacceptable today, such as EAF dust being  
 40 spread on fields as a “zinc supplement”.  
 41 This shows how fast the social, political and  
 42 economic definitions of waste evolve, al-  
 43 though they do not always necessarily in-  
 44 tersect. More recent IISI studies take an even  
 45 bolder and broader perspective, analysing  
 46 the production of steel in a life-cycle per-  
 47 spective, i.e. taking into account all the envi-  
 48 ronmental outcomes of the production of the  
 49 metal. We thus have an example of a grad-  
 50 ual broadening of (official) perspectives on  
 51 waste in the steel industry.  
 52

53 Many of these by-products do not pose  
 54 particular problems in terms of recirculation  
 55 due to their material properties: they are car-  
 56 bon or iron rich for instance, with little or  
 57 no undesirable substances, such as zinc or  
 58 lead, and are not difficult and/or costly to  
 59 collect and recirculate. Due to the unstable  
 60 cost of raw materials, it makes sense to try  
 61 and reduce coke consumption or losses of  
 62 iron-bearing materials.

1 However, as we shall see below, for vari-  
 2 ous reasons, not all materials can be reused:  
 3 some materials are problematical, or, rather,  
 4 have become so due to a conjunction of po-  
 5 litical and economic factors especially in the  
 6 last 20 years or so. These problem wastes,  
 7 and the symbolic, economic, environmental,  
 8 political and social mechanisms and issues  
 9 they reveal, are at the heart of this paper. We  
 10 want to build an understanding of how these  
 11 materials have been constructed as “prob-  
 12 lematical”, in the technological, economic  
 13 and social context of the contemporary steel  
 14 industry, and its current mutations.

### 15 **3 Methodology for analysing** 16 **“problem” wastes**

17 I now turn to the “problem wastes”, and  
 18 analyse the factors that make them such,  
 19 i.e. their material, but also social, political  
 20 and economic genesis. I also look at empir-  
 21 ical material showing how these wastes are  
 22 dealt with, practically and symbolically, by  
 23 the industry, regulators and other industry  
 24 experts ; in other terms, how the approach to  
 25 these materials is co-produced by a variety of  
 26 actors. The narrowing down of the vast array  
 27 of by-products and wastes produced by the  
 28 steel industry is based on interviews with  
 29 steel company executives and steel indus-  
 30 try consultants, as well as executives from  
 31 global waste management companies work-  
 32 ing for the steel industry. Moreover, there is  
 33 evidence in the literature documenting how  
 34 problematical these wastes are (see IISI [4],  
 35 for example).

36 One last point to have in mind before  
 37 looking in detail at the “problem” wastes (or  
 38 any waste produced by the steel industry  
 39 for that matter) is the extreme variability in  
 40 the quantities of waste produced, sometimes  
 41 from 1 to 20 or more (IISI [3] and IISI [4]), ac-  
 42 cording to the plant and the waste taken into  
 43 consideration. This is due to several factors,  
 44 including quality and type of raw materials,  
 45 age and maintenance of plant, processes, as  
 46 well as big differences in legislation (from  
 47 country to country, but also historically in a  
 48 given country), definition of materials, and  
 49 in the adoption of new technologies and/or  
 50 processes.

Moreover, the use of raw materials and 51  
 the subsequent production of wastes are 52  
 nonlinear processes (e.g. increased use of 53  
 raw materials required in blast furnace when 54  
 materials with high zinc content are used). 55  
 That’s why any understanding of waste in 56  
 the steel industry will have to be place and 57  
 time based to seize the historical and ge- 58  
 ographical differences: what is impossible 59  
 in a given time and place may be standard 60  
 practice at other times and places. However, 61  
 based on the existing literature (Schultmann 62  
 et al., [8]), and for the sake of clarity of anal- 63  
 ysis, we can assume that by-product gen- 64  
 eration is around 500 kg per tonne of steel 65  
 in the global North, due to multiple pollu- 66  
 tion abatement apparatuses, which for in- 67  
 stance transform emissions to the air into 68  
 solid wastes by scrubbing etc. These wastes 69  
 would therefore not exist without the latter 70  
 devices but would simply be uncontrolled 71  
 emissions. 72

#### (a) *Blast furnace filter cake* 73

The first “problem” waste we turn to is Blast 74  
 Furnace Filter Cake (FC). FC results, ulti- 75  
 mately, from the cleaning of BF off-gases 76  
 (not the gases from tapping, which are cap- 77  
 tured in a baghouse and recycled to the sin- 78  
 ter plant) by water-scrubbing. This sludge 79  
 contains heavy metals (lead, zinc, cadmium, 80  
 arsenic) and is very alkaline. Due to its high 81  
 content in heavy metals and water, it is not 82  
 readily recyclable through the production 83  
 process (sinter plant then BF), notwithstand- 84  
 ing its content in carbon and iron that makes 85  
 it potentially re-usable. Zinc (Zn) in partic- 86  
 ular is a problem in the BF because it re- 87  
 sults in extra coke consumption and there is 88  
 also a risk of scaffolding<sup>4</sup>: Zn evaporates be- 89  
 cause of the very high temperatures, then 90  
 condenses on the walls of the furnace at 91  
 lower temperature. The condensed Zn pre- 92  
 vents the descent of the furnace load, which 93  
 can lead to its sudden collapse, generating 94  
 large amounts of dust and possible dam- 95  
 age to the BF. Moreover, alkaline substances, 96  
 such as sodium and potassium, can have 97

<sup>4</sup> The maximum admissible Zn content per 74  
 tonne of hot metal in the BF is estimated to be 75  
 between 0.1 and 0.45 kg according to IISI [4]. More 76  
 recent studies place it at an average of 120 g/t 77  
 (0.12 kg). 78

1 negative repercussions on hot metal prop-  
2 erties.

3 In the plants I studied, this waste stream  
4 used to be landfilled, but this is now impos-  
5 sible since a ban on liquids going to land-  
6 fills, and also due to its heavy metal content:  
7 the material properties of the waste (both  
8 its chemical composition and its state, i.e. a  
9 liquid) therefore interfere, in the context of  
10 a changing regime of waste management,  
11 with its traditional fate, creating a bottle-  
12 neck in the flow of materials from "cradle  
13 to grave". Of the several thousand tonnes  
14 produced every year, 60% was processed  
15 internally via the hydrocyclone process fol-  
16 lowed by the sinter plant, to reclaim Fe and  
17 C units. The remaining 40% was dewatered  
18 on plant by a contractor. Dewatering leaves  
19 a solid residue and a liquid one mainly con-  
20 stituted of water, which is left to settle in  
21 lagoons on the site, the water then being dis-  
22 charged via the wastewater plant. We thus  
23 see that the process of dealing with this sub-  
24 stance has undergone increasing complex-  
25 ification, from "simple" dumping in holes,  
26 to separating streams. Things do not stop  
27 here, however, as the solid fraction cannot  
28 be disposed of to landfill, because it is of-  
29 ficially classified as hazardous, due to its  
30 heavy metal content, but also to naturally-  
31 occurring radioactivity: FC contains Pb-210  
32 and Pl-210 (isotopes of lead and polonium  
33 respectively), and therefore cannot be reused  
34 in the production process (BF and/or sinter  
35 plant) as this would concentrate radioactiv-  
36 ity even more. A small fraction, via briquet-  
37 ting and blending with other by-products,  
38 can be reused in the BOS plant, plant oper-  
39 ators are unwilling to increase this prop-  
40 ortion due to cooling effects. Another issue  
41 is the fact that, according to a contractor in  
42 charge of a briquetting plant, the FC was  
43 not being sufficiently dewatered by the con-  
44 tractor in charge of the latter, meaning that  
45 more processing had to take place before  
46 the FC could actually be briquetted. Most  
47 of the FC was thus stockpiled on plant. This  
48 stockpiling was a growing problem, espe-  
49 cially at another plant where there were sig-  
50 nificant legacy piles due to the absence of  
51 landfill availability. Some executives of the  
52 plant saw a solution to these stockpiles in  
53 the Rotary Hearth Furnace process which

volatilises the Zn and Pb contained in BF  
filter cake, leaving the iron oxide, whilst con-  
centrated Zn and Pb units can be recovered  
and then sold. However more senior plant  
managers were not interested in pursuing  
this avenue, opting for other outlets, such as  
using blast furnace filter cake in the cement  
industry.

In this case, we see that it is the change  
in legislation that, initially, made the waste  
a "problem", because it just used to be  
dumped before, without any "problems" for  
anyone : the material just did not really ap-  
pear on anyone's radar. It was not even the  
same waste in a certain way, as the dewater-  
ing of the sludge creates two streams of  
waste, one solid and one liquid, where there  
used to be a single (liquid) one. The neces-  
sity to deal differently with a substance that  
used to be "simply" landfilled fully reveals  
the problematical material properties of the  
filter cake, i.e. its high content in unwanted  
substances, that seem to be revealed by the  
necessity to dewater it (as a plant executive  
puts it, "we used to have a non-hazardous  
fluid, now we have two hazardous waste  
streams"). The steel production process, in  
its present state, cannot cope with this added  
source of Zn, but not only for material rea-  
sons: there is a reticence to reorganise pro-  
duction to accommodate this material (in the  
BOS plant, where it would not pose so much  
of a material problem, but an organisational  
one, due to a cooling effect, instead of the BF),  
and the industry are therefore stuck with a  
growing stockpile of the "stuff".

### (b) *Oily millscale sludge*

The second problem waste was oily millscale  
sludge. Rolling steel requires the use of oil  
(to lubricate) and water (as a coolant); the  
two combine with millscale to form a sludge  
from the oxidation of steel; most of this  
millscale is not contaminated with oil and  
can be readily recycled to the sinter plant due  
to its high FeO<sub>x</sub> (iron oxide) content. Several  
thousand tonnes of the oily type were pro-  
duced every year at one of the steel plants  
I studied. The sinter plant could not take  
this material, although it is rich in iron ox-  
ide, because the presence of oil would have  
caused a potential fire hazard, on the one  
hand, and, on the other hand, emissions

1 from the sinter plant would have been in  
 2 breach of opacity standards. Various exper-  
 3 iments were carried out to remove the oil,  
 4 such as bio-remediation (also attempted in  
 5 the USA), or the construction of a dedicated  
 6 solution at another plant, for £3 m. The mate-  
 7 rial was also being dewatered, and the solid  
 8 fraction was landfilled. According to an ex-  
 9 ecutive, "no one has a real solution to this,  
 10 we're just making it into a non-liquid" to  
 11 be able to landfill it. Here again, legislation  
 12 combined with the material properties of the  
 13 substance to create a "problem waste", al-  
 14 though, in this case, the flexibility of the def-  
 15 inition of a "waste" (and even more so of  
 16 a "hazardous waste") was illustrated by the  
 17 fact that this substance had gone from haz-  
 18 ardous to non hazardous, once again em-  
 19 phasising the fact that the same materials  
 20 can travel through several conceptual cate-  
 21 gories based on the capacity of the industry  
 22 to negotiate with regulators.

23 **(c) Electro-static precipitator dust**

24 The third "problem" waste was Electro-  
 25 Static precipitator (ESP) dust, from the sinter  
 26 plant (there is also an ESP at the steelplant,  
 27 but it did not produce any problem wastes).  
 28 The ESP is the most commonly used dust  
 29 abatement technique. However, the compo-  
 30 sition of sinter plant dust hinders the opti-  
 31 mal operation of the ESP: the dust contains  
 32 heavy metals, is alkaline and radioactive<sup>5</sup>.  
 33 Part of it is reused in the briquetting plant  
 34 ,but the contractor are now saying that they  
 35 have too much ESP dust in their mix and  
 36 so cannot take it all. Part of it can also be  
 37 re-used in the sinter plant itself (the sinter  
 38 plant is one of the main routes for the recy-  
 39 cling of reverts in the steel industry, with up  
 40 to 85% of all in-plant recycling<sup>6</sup>), however  
 41 there is a limit to how much the sinter plant  
 42 can take, as it was not designed first and fore-  
 43 most to be a waste disposal route, but part

<sup>5</sup> The radioactivity of sinter plant emissions was first identified in the Netherlands, and derives from the presence of trace amounts of uranium and thorium, and their decay products in the iron ores and coals used for ironmaking. The main isotopes emitted during sintering are lead-210 and polonium-210, which become concentrated in the waste gas.

<sup>6</sup> IISI seminar on sinter & pellets [5].

of an integrated steelmaking process. This  
 dust is hazardous due to its composition of  
 course, but also its consistency which makes  
 it difficult and dangerous to deal with: it is  
 very fine and very dry dust and handling  
 it would require very qualified personnel;  
 also, any kind of dust (especially fine) needs  
 to be agglomerated before it can be used in  
 any process, adding to the complexity and  
 cost of dealing with waste. This dust is cur-  
 rently being stored.

**(d) Lead-containing waste**

Lead-containing steel is used by the automo-  
 bile industry for its machineability. A lot of  
 the lead is lost in the production process: one  
 third is contained in the fumes released dur-  
 ing production. These fumes are treated via  
 bag filters, which collect high-lead dust (60–  
 70% lead content, 20% of the dust) and low-  
 lead dust (around 10% lead content, 80% of  
 the dust). Around 200 tonnes of dust are pro-  
 duced per year at the plant studied. This dust  
 is difficult to deal with, firstly because, ob-  
 viously, it is highly toxic, and also because  
 it is very dry and will not readily dissolve  
 to form a sludge when treated with water;  
 instead, it forms little balls that can explode  
 at any time and release the hazardous dust,  
 making it hard to handle (versus dewatering  
 BF cake for instance, which is standard prac-  
 tice). The low-lead dust used to be landfilled  
 on site, but this was now prohibited, and  
 hazardous wastes landfill sites were deemed  
 "too expensive". The high-lead dust used to  
 be sent to smelters, which have now closed,  
 so the dust was being shipped "to the Far  
 East" as this is cheaper than landfilling;. Here,  
 we see that a combination of legal and econ-  
 omic factors contribute to placing the lead-  
 containing waste in an international political  
 economy of waste, as it is cheaper to ship  
 "to the Far East" than landfill it in special-  
 ised landfills in higher cost countries. More-  
 over, the domestic industry that used to  
 handle this waste had shut down, illustrat-  
 ing the reliance on international circuits. An-  
 other aspect of the question is that, in prac-  
 tical terms, more lead-containing dust could  
 be recycled on plant, but this would imply  
 some organisational changes. The company,  
 following industry-wide practice, chose to  
 concentrate on its "core job" in an effort to

1 cut costs, which can be witnessed in the use  
 2 of contractors for more and more operations,  
 3 and the subdivision of activities among sev-  
 4 eral contractors to drive prices down.

5 **(e) Dust from electric arc furnaces (EAF)**

6 This is generated during the production of  
 7 steel in EAF plants. Several thousand tonnes  
 8 were produced every year by certain plants.  
 9 The dust is captured in filters in baghouses.  
 10 The problem with this dust, once again, is its  
 11 Zn content. It could be landfilled until a few  
 12 years ago, when this practice was banned.  
 13 Attempts to use this dust in the briquetting  
 14 plant after concentration had proven uneco-  
 15 nomical: Zinc smelters consistently try to get  
 16 a higher zinc content while demanding to  
 17 pay less, or even to be paid, to take the dust.  
 18 So this dust was being shipped abroad, to  
 19 be used in the production of cement, failry  
 20 standard practice in the industry (IISI [3] and  
 21 IISI [4]). Once again, we see the international  
 22 circuits of waste, and how they can be mo-  
 23 bilised by steel companies to, in a way, evade  
 24 costly domestic regulations, and also deal  
 25 with materials for which there is no infras-  
 26 tructure in the country of origin.

27 **4 Conclusions**

28 Many factors preclude the optimal reuse of  
 29 various by-products arising during the pro-  
 30 duction of steel. These by-products become  
 31 wastes, materials with no obvious applica-  
 32 tions, and they are also a liability. They all re-  
 33 quire relatively costly and time-consuming  
 34 pretreatment to be reused in the integrated  
 35 processes, and/or contain unwanted sub-  
 36 stances such as zinc and other heavy metals  
 37 that can hinder the process and affect prod-  
 38 uct quality. Also, the physical characteris-  
 39 tics of the wastes (oily sludge or very fine-  
 40 grained material) can preclude their reuse.  
 41 All in all, this illustrates the fact that the  
 42 components of the steel plant are designed  
 43 primarily to produce steel, and not to re-  
 44 cycle wastes: there are limits to how much  
 45 of these wastes they can handle, and only  
 46 materials containaing desirable substances  
 47 (FeOx, C, fluxes) are readily recyclable. This  
 48 makes the idea of separate waste process-  
 49 ing routes<sup>7</sup>, such as rotary hearth furnace

<sup>7</sup> As well as the insertion of wastes in interna-  
 tional circuits, as already noted before.

processes or variants thereof, potentially ap-  
 pealing, though this can be seen as non-core  
 business.

53 However, more than the availability and  
 54 cost of technology, problems surrounding  
 55 these materials also come down to organi-  
 56 sational issues, such as the resistance to us-  
 57 ing more briquettes, or the selection of in-  
 58 adapted processes by contractors who are  
 59 often asked to manage more and more by-  
 60 products at an ever lower cost. Furthermore,  
 61 recyclates are not necessarily reused. Indeed,  
 62 one of the plants investigated wasn't actu-  
 63 ally using its briquettes, due to their higher  
 64 cooling effect when compared to scrap, al-  
 65 though they are cheaper. Thus, the briquettes  
 66 were just piling up, posing the question of  
 67 whether there is any real commitment to  
 68 reusing the materials in question, and at any  
 69 rate leading to the loss of recoverable ma-  
 70 terials. The company preferred to pay third  
 71 parties to take these materials and ship them  
 72 abroad, and recover the values themselves,  
 73 than modify some of its processes to accom-  
 74 modate these materials.

75 It is thus clear that social sciences have  
 76 something to say, as all is not down to tech-  
 77 nology, but also to the way it is integrated (or  
 78 not) into organisational routines, on the one  
 79 hand, and what the strategies behind the use  
 80 of these technologies are, on the other. Like-  
 81 wise, issues of knowledge building, codifi-  
 82 cation and transfer between companies or  
 83 even divisions of a given company, and be-  
 84 tween companies and contractors, are also  
 85 socially constructed. Therefore, the steel in-  
 86 dustry can be taken as an exemplar of the  
 87 necessity for social sciences and industry to  
 88 collaborate more often and on a wider array  
 89 of topics.
